About

This script covers the computational and bioinformatics parts of the module “Methods in Evolutionary Ecology”. We will introduce you to **R** and **BASH**, two of the most widely used scripting languages, and make you familiar with navigating in a UNIX environment. These skills are important for any biologist, irrespective of the field you may want to specialise in in the future. Building upon your new knowledge, we will learn how to reconstruct phylogenies from sequencing data, how to work with genomic data, and how to characterise microbiomes. At the end of three weeks computational work, you will tackle a small computational group project, putting your new skills into practise.

The script is designed to cover the entire course content. While we will go you through all of the material together in detail during the course, the script should also enable you to work through the content on your own, e.g., to recap after the course has finished and as a reference and starting point for future computational endeavours.

Quarto

The text is formatted using [Quarto](#), which comes with a number of benefits. It allows us to provide explanations as structured and nicely formatted regular text, and to include code blocks for all computational steps. When compiling Quarto documents, all of the code is run, which means that you not only see the code, but also the outputs it creates.

Here is an example:

This little block of **R** code generates 100 random coordinates and plots them. The code is shown below, together with the output the code has produced (in this case, a plot).

```
x <- runif(100)
y <- runif(100)
plot(x, y)
```

The code can conveniently be copied from the block into your own scripts.

Quarto supports many formats, we here provide the script as a webpage and a printable pdf. Writing Quarto documents is very simple and can be done using RStudio as an editor. The entire script is available for you on [github](#) – feel free to download it and modify it with your own comments, notes, and code. We will provide a short introduction to github and Quarto in the course.

How to find your way around

Simply use the navigation on the left to quickly access the different topics, or flip through the individual pages using the buttons at the bottom of the page. You may wish to download the pdf version of the script (click the pdf icon in the top left) which is ideal for printing. The script is organized by topics, rather than course days, because we will adapt the tempo according to your needs.

Please note: The script will very likely only be complete at the end of the course. We will still be modifying and correcting it throughout the three weeks you are with us. So make sure to check out the final version at the end of the course.

Part I

R

1 First steps

R is a statistical programming environment that has become a standard tool in the data and life sciences and many other fields. You may have used R already to run some statistics in a course you took in your studies, and this will be a likely use case for your remaining degree. However, R is much more: it can be used to analyse massive the datasets of the “omics”- age, build webpages, blogs, and interactive apps, and even for art!

Before taking full advantage of what the various R packages have to offer, we need to become familiar with its basic structure and commands. It pays off to invest a little effort in practicing the basics, because all R packages use the same syntax – a solid familiarity with base R thus allows you to explore the entire R universe independently.

1.1 Operators and functions

R can be used just like an arithmetic calculator. You are familiar with all of the basic syntax already, if you know how to use a calculator!

Some examples:

```
3 + 4
```

```
[1] 7
```

```
3 - 4
```

```
[1] -1
```

```
3 * 4
```

```
[1] 12
```

```
3 / 4
```

```
[1] 0.75
```

```
3 ^ 4 # power of
```

```
[1] 81
```

As with a regular calculator, there is operator precedence: power > multiplicative operations > additive operations:

```
(1 + 2) * 3
```

```
[1] 9
```

```
2^3 * 3
```

```
[1] 24
```

```
2^(3 * 3)
```

```
[1] 512
```

Square roots, exponentials, and logarithms also work just as with a calculator:

```
sqrt(9)
```

```
[1] 3
```

```
exp(3)
```

```
[1] 20.08554
```

```
log(3)
```

```
[1] 1.098612
```

```
log(exp(3)) # natural logarithm
```

```
[1] 3
```

```
log10(100) # logarithm to base 10
```

```
[1] 2
```

In order to “save” a value for use later on, you have to assign it to a variable! `<-` is the assignment operator you need to use for this (handy shortcut in RStudio is `ALT + -`).

```
x <- 3 + 4
```

Calling the variable will then print the result to the R console, and can be used in other calculations.

```
x
```

```
[1] 7
```

```
x + 10
```

```
[1] 17
```

You can call your variables whatever you want, but be careful: R will overwrite any variable if you tell it to, without a warning! You should also avoid giving your variables names that are already assigned to functions.

```
my_favourite_variable <- 100  
my_favourite_variable <- 50  
my_favourite_variable
```

```
[1] 50
```

All variables (among other things) are visible in the environment panel in RStudio (default: top right part of the screen).

“=” can also be used to assign variables but is discouraged, because the direction of the assignment is not immediately obvious. It is best practise to always start with the variable, followed by the assignment operator

1.2 Data types

You need to be familiar with at least three important data types in R: **logical**, **numeric**, and **character**. Data being stored in a different data type than required is one of the most frequent error messages you will encounter as an R beginner.

logical simply means true or false. R also understands the abbreviations T and F. To determine which types your data is in, you can use **mode** or **class**.

```
var1 <- TRUE
mode(var1)
```

```
[1] "logical"
```

numeric means numbers

```
var2 <- 10
class(10)
```

```
[1] "numeric"
```

A character is any form of text, a so called “string”. It must always be surrounded by quotation marks!

```
var3 <- "A so called string"
mode(var3)
```

```
[1] "character"
```

If in doubt, R will often convert or read in data as characters. Watch out for some common errors!

```
var4 <- "5"
var4
```

```
[1] "5"
```

```
is.numeric(var4)
```

```
[1] FALSE
```

```
var5 <- "TRUE"  
var5
```

```
[1] "TRUE"
```

```
is.logical(var5)
```

```
[1] FALSE
```

You can convert between types easily!

```
var6 <- as.numeric(var4)  
var6
```

```
[1] 5
```

```
class(var6)
```

```
[1] "numeric"
```

1.3 Exercises

- a) Sum the values of 1 to 5
- b) Create a variable v1 and assign it a character value
- c) Copy variable v1 to v2
- d) Compare the value of v1 against v2

Tip

Compare values and variables using the following operators

| | |
|----|--------------------------|
| < | less than |
| <= | less than or equal to |
| > | greater than |
| >= | greater than or equal to |

`==` equals
`!=` not equal

Please note, `=` and `==` do very different things! Don't mix them up.

2 Data structures

So far we've only looked at simple variables consisting of a single value or character. Typically, your data will be more complex. In R, there are three structures relevant for the data you will be working with.

2.1 Vectors

A **vector** is a number of elements of the same data type (`logical`, `numeric`, `character`). It can be generated by concatenating the elements using the function `c`.

```
vec1 <- c(T, F, T, F)
vec1
```

```
[1] TRUE FALSE TRUE FALSE
```

```
mode(vec1)
```

```
[1] "logical"
```

```
vec2 <- c(1, 2, 3, 4, 5)
vec2
```

```
[1] 1 2 3 4 5
```

```
mode(vec2)
```

```
[1] "numeric"
```

```
vec3 <- c("Spring", "Summer", "Autumn", "Winter")
vec3
```

```
[1] "Spring" "Summer" "Autumn" "Winter"
```

```
mode(vec3)
```

```
[1] "character"
```

Other ways to generate vectors are `rep` and `seq`. `rep` is used to repeat any number of elements any number of times.

```
rep(5, 10)
```

```
[1] 5 5 5 5 5 5 5 5 5 5
```

```
rep(vec3, 5)
```

```
[1] "Spring" "Summer" "Autumn" "Winter" "Spring" "Summer" "Autumn" "Winter"
[9] "Spring" "Summer" "Autumn" "Winter" "Spring" "Summer" "Autumn" "Winter"
[17] "Spring" "Summer" "Autumn" "Winter"
```

`seq` can be used to create numerical sequences.

```
seq(from = 0, to = 100, by = 5)
```

```
[1] 0 5 10 15 20 25 30 35 40 45 50 55 60 65 70 75 80 85 90
[20] 95 100
```

The command above is easy to read and understand for humans, which is good. R will also understand if you specify it as

```
seq(0, 100, 5)
```

```
[1] 0 5 10 15 20 25 30 35 40 45 50 55 60 65 70 75 80 85 90
[20] 95 100
```

As a shortcut for a common sequences, you can use

```
1:10
```

```
[1] 1 2 3 4 5 6 7 8 9 10
```

As mentioned above,, vectors can only combine elements of a single data type. Combining multiple different data types may result in some unwanted behaviour.

```
vec_mix1 <- c(5, TRUE, 65)
mode(vec_mix1)
```

```
[1] "numeric"
```

```
vec_mix2 <- c("blue", TRUE, "red")
mode(vec_mix2)
```

```
[1] "character"
```

In many cases you may wish to access a single element of a vector. You can do so using square brackets.

```
z <- c("order", "family", "genus", "species")
z[2]
```

```
[1] "family"
```

Similarly, you can access any combination of elements from the vector.

```
z[1:2]
```

```
[1] "order" "family"
```

```
i <- c(1, 3)
z[i]
```

```
[1] "order" "genus"
```

```
z[c(1, 1, 1, 4)]
```

```
[1] "order" "order" "order" "species"
```

```
z[-1]
```

```
[1] "family" "genus" "species"
```

The square brackets are also used if you need to change elements of the vector. Changes are made using the assignment operator which you already know.

```
x <- 1:5  
x
```

```
[1] 1 2 3 4 5
```

```
x[c(1, 4)] <- 10  
x
```

```
[1] 10 2 3 10 5
```

Which elements of a vector have certain characteristics? This is important for filtering/selecting in your dataset. You can combine different queries using logical operators.

```
x >= 5
```

```
[1] TRUE FALSE FALSE TRUE TRUE
```

```
x[x >= 5]
```

```
[1] 10 10 5
```

```
which(x >= 5)
```

```
[1] 1 4 5
```

```
z
```

```
[1] "order" "family" "genus" "species"
```

```
which(z == "genus")
```

```
[1] 3
```

```
z[z== "genus"]
```

```
[1] "genus"
```

```
z[z != "genus"]
```

```
[1] "order" "family" "species"
```

```
which(z== "genus" | z == "order")
```

```
[1] 1 3
```

Logical operators in R

| | |
|---|-----|
| | OR |
| & | AND |
| ! | NOT |

Conveniently, the elements of a vector can be named and accessed using the names. Let's first create a vector...

```
dmel <- c("Hexapoda", "Diptera", "Drosophilidae", "Drosophila", "Drosophila melanogaster")
dmel
```

```
[1] "Hexapoda"          "Diptera"
[3] "Drosophilidae"     "Drosophila"
[5] "Drosophila melanogaster"
```

... and then add names for each element

```
names(dmel) <- c("Class", "Order", "Family", "Genus", "Species")
dmel
```

| | | | |
|--|--------------|---------------------------|-----------------|
| | Class | Order | Family |
| | "Hexapoda" | "Diptera" | "Drosophilidae" |
| | Genus | Species | |
| | "Drosophila" | "Drosophila melanogaster" | |

```
str(dmel)
```

```
Named chr [1:5] "Hexapoda" "Diptera" "Drosophilidae" "Drosophila" ...
- attr(*, "names")= chr [1:5] "Class" "Order" "Family" "Genus" ...
```

Now we can use the names to access the values

```
dmel[c("Class", "Species")]
```

| Class | Species |
|------------|---------------------------|
| "Hexapoda" | "Drosophila melanogaster" |

```
dmel[names(dmel) == "Order"]
```

| Order |
|-----------|
| "Diptera" |

2.1.1 Exercises

- Create a vector consecutively numbering all days of the year 2026. Assign the correct weekday names for all elements of the vector.
- Use the vector to determine how many days in 2026 are weekend days.

Tip

If you struggle to assign the correct names, have a look at the help for `rep`.

2.2 Matrices

A **matrix** in R can be thought of as a two-dimensional vector. All elements must be of the same data type. There are various ways to create a matrix. For example, one can use the `matrix` function like this.

```
mat1 <- matrix(data = 1:12, nrow = 3, ncol = 4, byrow=T)
mat1
```

| | [,1] | [,2] | [,3] | [,4] |
|------|------|------|------|------|
| [1,] | 1 | 2 | 3 | 4 |
| [2,] | 5 | 6 | 7 | 8 |
| [3,] | 9 | 10 | 11 | 12 |

Alternatively, a vector can be transformed into a matrix

```
mat2 <- 1:12
dim(mat2) <- c(3, 4)
mat2
```

```
      [,1] [,2] [,3] [,4]
[1,]    1    4    7   10
[2,]    2    5    8   11
[3,]    3    6    9   12
```

Often you will want to combine multiple vectors into a matrix

```
dmel <- c("Hexapoda", "Diptera", "Drosophilidae", "Drosophila", "Drosophila melanogaster")
dhyd <- c("Hexapoda", "Diptera", "Drosophilidae", "Drosophila", "Drosophila hydei")
mat3 <- cbind(dmel, dhyd)
mat3
```

```
      dmel                      dhyd
[1,] "Hexapoda"                "Hexapoda"
[2,] "Diptera"                  "Diptera"
[3,] "Drosophilidae"            "Drosophilidae"
[4,] "Drosophila"                "Drosophila"
[5,] "Drosophila melanogaster" "Drosophila hydei"
```

```
mat4 <- rbind(dmel, dhyd)
mat4
```

```
      [,1]      [,2]      [,3]      [,4]
dmel "Hexapoda" "Diptera" "Drosophilidae" "Drosophila"
dhyd "Hexapoda" "Diptera" "Drosophilidae" "Drosophila"
      [,5]
dmel "Drosophila melanogaster"
dhyd "Drosophila hydei"
```

Just like vectors, matrix elements can have names

```
mat3
```

| | dmel | dhyd |
|------|---------------------------|--------------------|
| [1,] | "Hexapoda" | "Hexapoda" |
| [2,] | "Diptera" | "Diptera" |
| [3,] | "Drosophilidae" | "Drosophilidae" |
| [4,] | "Drosophila" | "Drosophila" |
| [5,] | "Drosophila melanogaster" | "Drosophila hydei" |

```
colnames(mat3)
```

```
[1] "dmel" "dhyd"
```

```
rownames(mat3) <- c("Class", "Order", "Family", "Genus", "Species")
mat3
```

| | dmel | dhyd |
|---------|---------------------------|--------------------|
| Class | "Hexapoda" | "Hexapoda" |
| Order | "Diptera" | "Diptera" |
| Family | "Drosophilidae" | "Drosophilidae" |
| Genus | "Drosophila" | "Drosophila" |
| Species | "Drosophila melanogaster" | "Drosophila hydei" |

And just like with vectors, we can use square brackets to access and replace values. Because there are 2 dimensions, we need to provide 2 values (one for rows, one for columns, separated by ,).

```
mat3
```

| | dmel | dhyd |
|---------|---------------------------|--------------------|
| Class | "Hexapoda" | "Hexapoda" |
| Order | "Diptera" | "Diptera" |
| Family | "Drosophilidae" | "Drosophilidae" |
| Genus | "Drosophila" | "Drosophila" |
| Species | "Drosophila melanogaster" | "Drosophila hydei" |

```
mat3[1:3, 2]
```

| Class | Order | Family |
|------------|-----------|-----------------|
| "Hexapoda" | "Diptera" | "Drosophilidae" |

```
mat3[1:3, ]
```

| | dmel | dhyd |
|--------|-----------------|-----------------|
| Class | "Hexapoda" | "Hexapoda" |
| Order | "Diptera" | "Diptera" |
| Family | "Drosophilidae" | "Drosophilidae" |

```
mat3[c("Class", "Species"), ]
```

| | dmel | dhyd |
|---------|---------------------------|--------------------|
| Class | "Hexapoda" | "Hexapoda" |
| Species | "Drosophila melanogaster" | "Drosophila hydei" |

2.2.1 Exercise

- create a matrix using with 20 rows & 5 columns, using 100 randomly generated numbers between 0 and 1000.
- replace all values in the 3rd column of this matrix that are larger than 500 with NA.

Tip

use the function `runif` to create random values

2.3 Data frames

Data frames are the R equivalent of spread sheets. Like matrices, they are two-dimensional, however they may combine different data types. Most biological data sets you will encounter will be data frames.

Lets create a data frame

```
# create some data
species <- rep(c("beech","ash","elm","maple", "sycamore"),40)
species
```

```

[1] "beech"      "ash"        "elm"        "maple"      "sycamore"   "beech"
[7] "ash"        "elm"        "maple"      "sycamore"   "beech"      "ash"
[13] "elm"        "maple"      "sycamore"   "beech"      "ash"        "elm"
[19] "maple"      "sycamore"   "beech"      "ash"        "elm"        "maple"
[25] "sycamore"   "beech"      "ash"        "elm"        "maple"      "sycamore"
[31] "beech"      "ash"        "elm"        "maple"      "sycamore"   "beech"
[37] "ash"        "elm"        "maple"      "sycamore"   "beech"      "ash"
[43] "elm"        "maple"      "sycamore"   "beech"      "ash"        "elm"
[49] "maple"      "sycamore"   "beech"      "ash"        "elm"        "maple"
[55] "sycamore"   "beech"      "ash"        "elm"        "maple"      "sycamore"
[61] "beech"      "ash"        "elm"        "maple"      "sycamore"   "beech"
[67] "ash"        "elm"        "maple"      "sycamore"   "beech"      "ash"
[73] "elm"        "maple"      "sycamore"   "beech"      "ash"        "elm"
[79] "maple"      "sycamore"   "beech"      "ash"        "elm"        "maple"
[85] "sycamore"   "beech"      "ash"        "elm"        "maple"      "sycamore"
[91] "beech"      "ash"        "elm"        "maple"      "sycamore"   "beech"
[97] "ash"        "elm"        "maple"      "sycamore"   "beech"      "ash"
[103] "elm"        "maple"      "sycamore"   "beech"      "ash"        "elm"
[109] "maple"      "sycamore"   "beech"      "ash"        "elm"        "maple"
[115] "sycamore"   "beech"      "ash"        "elm"        "maple"      "sycamore"

2.3.1 Exercise

- a) Using `df1`, select only entries corresponding to ash and maple with an age over 50 and a diameter less than 30.
- b) Add a new column to the dataframe called “year”. Generate data for this column so that there are 10 different years and the same number of entries for each tree species per year.

Tip

Use the function `rep` for this exercise

3 Data, packages, and some more functions

3.1 Setting up your working environment

Usually when working in **R**, you want to look at your own data, and not generate it from random distributions. To read in a data file, we first need to tell **R** where the working directory is located.

```
setwd("/home/of22haqi/Documents/TEACHING/MEE-WS25-26/")
```

The path will look different on your machine of course.

Now that `R` knows where to find it, we are ready to read in a data file.

```
# The table contains headers, and the fields are separated by commas
be <- read.table("data/butterfly_ecology.csv", header = TRUE, sep = ",")

# Let's have a glimpse at the data
head(be)
```

[illegible]

```
mean(be$range.size, na.rm = TRUE)
```

```
[1] 261.4116
```

`mean` is the function, `be$range.size` is the object (1 vector from the dataframe we just read into R) and `na.rm = TRUE` is the option to remove NAs from the vector before calculating the mean.

In some cases, you may want to do things to your data that cannot be addressed by a single function. In this case, you may have to perform a number of different operations on the dataset. If you are likely to use the same set of operations in the future, it may be advisable to use your own functions.

A very simple example. Let's assume the mean function didn't exist and we would need to write our own.

```
mean2 <- function(x){  
  x <- na.omit(x)  
  sum(x) / length(x)  
}  
  
mean2(be$range.size)
```

```
[1] 261.4116
```

We define `mean2` as a function that requires an object (here called `x` as an input). Looking into the function, we can see that it first removes the NAs from the object and next calculates the sum of `x` divided by the number of elements of `x` (this is how the mean is defined). Testing it, we can see that it gives the same result as the native mean function.

3.3 Loops

In many cases, we need to apply a function to a number of elements. In this case, loops come in handy. In the simple examples below, the structure of a for loop is illustrated.

```
for(i in 1:10) # how often is the loop repeated  
{  
  print(i)    # what is to be done each iteration  
}
```

```
[1] 1
[1] 2
[1] 3
[1] 4
[1] 5
[1] 6
[1] 7
[1] 8
[1] 9
[1] 10
```

```
j<-0
for(i in 1:5)
{
  j<-i+j
  print(j)
}
```

```
[1] 1
[1] 3
[1] 6
[1] 10
[1] 15
```

Observe and try to explain what happens in each iteration to the variables used in these examples.

3.4 Plots

For many use cases `ggplot2` is the best approach of plotting, and we will get to know this package later. However, for very simple and quick plots, base R plotting functions are sufficient and superior to other options because of simplicity and speed.

Scatter plots can be created by just naming the variables to be plotted against each other.

```
plot(be$WSP_Female_average, be$ALT_Range)
```

Histograms showing frequency distributions are also very easily generated

```
hist(be$WSP_Female_average)
```

3.5 Exercises

- a) Using a loop, plot histograms for the columns “WSP_Female_average”, “Alt_Range”, “Alt_min”, and “range.size”.
- b) Write a function that creates these plots with only the dataframe as argument.

4 Tidyverse

4.1 What is the tidyverse?

- A collection of R packages for data science
- All packages share a “philosophy” about design and data structure
- All packages are highly compatible and functions complement each other

We will only be looking at a couple of functions from a 2 packages (`dplyr` & `ggplot2`). All functions are about **data manipulation and visualisation** and are especially well suited for exploring very large data sets.

You can install all tidyverse packages by running

```
install.packages("tidyverse", dependencies = TRUE)
```

The following package(s) will be installed:

- tidyverse [2.0.0]

These packages will be installed into "~/work/MEE-WS25-26/MEE-WS25-26/renv/library/R-4.2/x86_64-pc-linux-gnu".

```
# Installing packages -----
- Installing tidyverse ... OK [linked from cache]
Successfully installed 1 package in 7.1 milliseconds.
```

Let's refresh what we learned earlier this week:

1. What different types of data structures are used in R?
2. Which of these do you think is most likely to be used in the `tidyverse`?

(Remember, you can just add the answers into this document for future reference!)

4.2 Our data set for today

We will be looking at a data set of ecological traits of european butterflies. Download the table and read it into R.

```
# The table contains headers, and the fields are separated by commas
be <- read.table("data/butterfly_ecology.csv", header = TRUE, sep = ",")

# Let's have a glimpse at the data
head(be)
```

[illegible]

Each of the rows contains data for 1 European species, and the columns contain the following information:

[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

The filtering criterion can be specified using the methods you are already familiar with (e.g., `>`, `>=`, `!=`, `%in%`).

Notice that the variable names can be used directly here, so instead of using `be$OWS_egg`, `filter()` lets you use `OWS_egg` directly. All **tidyverse** functions work like that. Let's look at more complex filtering:

```
# combine 2 filters with boolean "AND" ...
filter(be, OWS_egg == 1 , ALT_Min > 500)
```

[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

[illegible]

NOTE

`filter()` (and many other `tidyverse` functions) return a data frame. In the `tidyverse`, these are called `tibble()` and behave slightly different to regular data frames. For our purposes however, these differences are not important.

4.4 The pipe %>% for combining commands

The filtering using `filter()` is very useful, but you can see that the commands can become very long when you have many filters. Also, trying out many different filters to see what they do with the data can be cumbersome. This where `%>%` comes in really handy.

The “pipe” `%>` (keyboard shortcut: **Ctrl+Shift+M**) simply passes the result of one function to the next function. For the next function, one does not have to specify the data frame. Let’s see an example.

```
# this is how we filtered our data frame earlier
filter(be, OWS_egg == 1)
```

[illegible]

[illegible]

```
# Multiple filters are connected by pipes
be %>%
  filter(OWS_egg == 1) %>%
  filter(LEV_ground_layer == 1) %>%
  filter(AFB_honeydew == 1)
```

```
# As always in R, assign the result to a new variable using "<-"
be_filtered <- be %>%
  filter(OWS_egg == 1) %>%
  filter(LEV_ground_layer == 1) %>%
  filter(AFB_honeydew == 1)
```

4.5 Sort by column with arrange()

This doesn't change the dataframe itself, it simply orders the columns (similar to the sort function in Excel):

```
# sort by age (ascending) and weight (descending)
be %>%
  arrange(conserv.eu, -range.size)
```

Functions like `contains` can be powerful for filtering and selecting. `starts_with` and `ends_with` work just the same way and are equally useful.

4.7 Create new variables with `mutate()`

This is a very powerful and flexible function that uses existing variables to create novel ones. Let's look at a simple example

| OWS_juvenile | OWS_adult |
|--------------|-----------|
| 1 | 0 |
| 1 | 0 |
| 1 | 0 |
| 1 | 0 |
| 1 | 0 |
| 1 | 0 |
| 1 | 0 |
| 0 | 1 |
| 0 | 1 |

```
# Determine how different the protection levels between EU and Europe and extract the species
be %>%
  mutate(protect_diff = abs(conserv.europe - conserv.eu)) %>%
  filter(protect_diff > 2)
```

| | con- | WSP_Fe- | GEN_Av- | male_av- | FM_Av- | AFB_Av- | an- | AFB_min- | overdiff |
|---------------------------|---------|---------|---------|----------|--------|---------|------|----------|--------------------|
| species | range | size | OVS | OVS | GEN | GEN | GEN | GEN | GEN |
| Coccyzus erythrophthalmus | 528-510 | 0 | 1.00 | 1.00 | 0.38 | 0 | 0.25 | 0 | 1 0 0 1 0 0 0 500 |
| Lycaena tityrus | 142-110 | 0 | 1.25 | 1.50 | 0.52 | 4 | 0 | 0.28 | 90 1 0 0 1 0 0 100 |
| Tommyrus septentrionalis | 23-10 | NAN | 1.00 | 1.00 | 0.32 | 5 | 1 | 0 | 0 0 0 0 0 0 0 230 |

4.8 Exercise

- From our dataset, filter out all butterflies with average wingspans larger than 60mm and smaller than 30mm. Only keep the species that have a conservation classification on the EU level. Only keep the species names and all variables associated with adult feeding, and store this in a new data frame. How many rows and columns does the new data frame have?
- Re-calculate the generation range from the provided minima and maxima. Check if your calculations match the original range values given in the data.

4.9 group_by() and summarise() as powerful data exploration tools

Although `dplyr` has a simpler syntax overall, everything we have looked at so far could have been done fairly easily with base R functions: data frame filtering, sorting, and adding and removing columns. One of the strengths of `dplyr` is explorative data analysis, and this is where `group_by()` and `summarize()` are really helpful. We'll only look at very simple examples today.

When browsing through the complete data table, it is very hard to recognize any patterns. Let's assume we wanted to compare the average wing span of butterflies with that overwinter as adults vs all other butterflies:

```
# Are butterflies that overwinter as adults larger than other species?
be %>%
  drop_na() %>%
  group_by(OWS_adult) %>%
  summarise(mean_wsp = mean(WSP_Female_average))
```

| OWS_adult | mean_wsp |
|-----------|----------|
| 0 | 39.42489 |
| 1 | 51.85294 |

After choosing which variable to group by (here: `OWS_adult`), `summarise()` then calculates a function for each group. In our simple example, there are 2 groups: 0 (not overwintering as adult) and 1 (overwintering as adult); and the function to be calculated is the mean of the female wing span. This is a very flexible set of functions, because you can group by multiple groups and also use `summarise()` with many different functions (e.g., `mean()`, `sum()`, `min()`, `max()`, `median()` – just to name a few). Let's look at a more complex example:

```
# Let's add another group. How large is the standard deviation? How large is each group?
be %>%
  drop_na() %>%
  group_by(OWS_adult, LEV_ground_layer) %>%
  summarise(mean_wsp = mean(WSP_Female_average),
            sd = sd(WSP_Female_average),
            group_size=n())
```

``summarise()`` has grouped output by `'OWS_adult'`. You can override using the ``.groups`` argument.

| OVS_adult | LEV_ground_layer | mean_wsp | sd | group_size |
|-----------|------------------|----------|-----------|------------|
| 0 | 0 | 38.12174 | 12.312380 | 115 |
| 0 | 1 | 40.69492 | 12.181504 | 118 |
| 1 | 0 | 54.26667 | 9.460192 | 15 |
| 1 | 1 | 33.75000 | 12.374369 | 2 |

4.10 More exercises

Using `dplyr` functions, determine

- If butterflies overwintering as pupae have higher level of legal protection
- If butterflies occurring at higher altitudes on average have a higher level of protection
- If feeding on honeydew is more common in larger butterflies.
- How many butterfly species are there per family?

For a–c also determine how many species belong to each group.

5 The ggplot2 package

5.1 Very (!) brief introduction

ggplot2 is a graphing library, i.e., a tool to make graphs in R. Compared with base graphs and other graphics packages, it comes with a number of advantages:

- Beautiful!
- Highly customizable (which is not always necessary though)
- Easiest way to create very complex plots
- Tightly integrated into the **tidyverse**

Compared with other packages the major drawbacks would be that it comes with a steep(ish) learning curve and is probably less intuitive for beginners. The reason is that **ggplot2** doesn't have fixed commands for scatterplots, boxplots, barplots, etc, but rather creates the plot in layers. The most important elements (or layers) of a plot in **ggplot2** are:

- *Data*: as we are still in the **tidyverse**, this is always a data frame
- *Aesthetics*: i.e., **what** you want to plot. Often, this will correspond to variables (columns) in your dataframe
- *Geometric objects*: i.e., **how** you want to plot the data. This can be points, bars, boxplots, lines, etc..
- *Facets*: more about this later
- *Additional (optional) adjustments*: this includes themes that specify the overall design

5.2 Building up the plot

We will start off with a very simple scatterplot and gradually increase the complexity to illustrate **ggplot2** functionality.

```
# data and packages
library(tidyverse, quietly = TRUE)
```

```
-- Attaching core tidyverse packages ----- tidyverse 2.0.0 --
v dplyr      1.1.4      v readr      2.1.6
v forcats    1.0.1      v stringr    1.6.0
v ggplot2    4.0.1      v tibble     3.3.1
v lubridate  1.9.4      v tidyr      1.3.2
v purrr      1.2.1
-- Conflicts ----- tidyverse_conflicts() --
x dplyr::filter() masks stats::filter()
x dplyr::lag()     masks stats::lag()
i Use the conflicted package (<http://conflicted.r-lib.org/>) to force all conflicts to become
```

```
be <- read.table("data/butterfly_ecology.csv", header = TRUE, sep = ",")

# simple plot
be %>%                                # DATA
  ggplot(aes(x = WSP_Female_average, # AESTHETICS
             y = range.size))
```

In the above example, the data is the data frame that we have been using the whole time. Notice how we can simply pipe it to `ggplot2`. `aes` specifies our aesthetics, i.e., **what** we want to plot. What is missing?

```
# simple scatter plot
be %>%                                # DATA
  ggplot(aes(x = WSP_Female_average, # Aesthetics
             y = range.size)) +
  geom_point()                        # Geometric object
```

The geometric object, i.e., **how** we want to plot our aesthetics. Notice that elements in `ggplot2` are added with the `+` symbol (this is specific to `ggplot2`). We can add more geometric objects that will use the same aesthetics:

```
# lets add another geom (a regression line), and also change the theme
be %>%                                # DATA
  ggplot(aes(x = WSP_Female_average, # Aesthetics
             y = range.size)) +
  geom_point() +                      # Geometric object
  geom_smooth(method = "lm") +        # Another geometric object
  theme_light()                      # Let's also change the theme
```

``geom_smooth()`` using formula = `'y ~ x'`

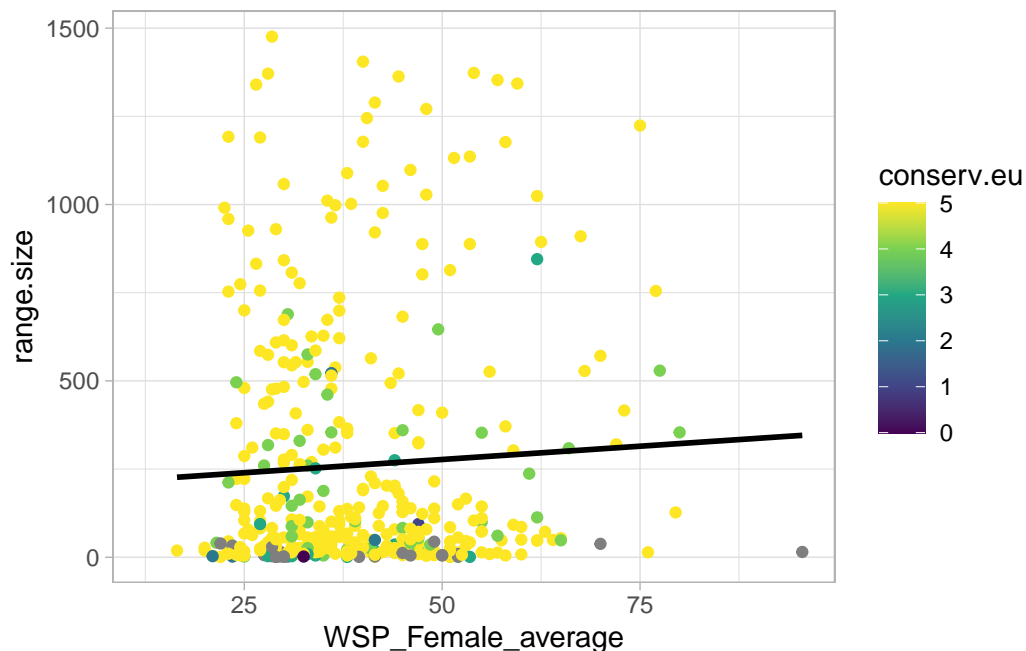

Changing the theme changes many layout options. For different applications, different themes might be appropriate. There are many additional themes available through packages such as [ggthemr](#) or [ggthemes](#).

A bit more on aesthetics: have you noticed that you only specify x and y once, and all geoms know **what** you want to plot. You can also specify additional aesthetics for each geom.

```
# Add additional aesthetics, here: we want to plot the sonsevation status. How? With colour

be %>%                                # DATA
  ggplot(aes(x = WSP_Female_average,    # Aesthetics
             y = range.size)) +
  geom_point(aes(color = conserv.eu)) + # aesthetics specific to the points only
  geom_smooth(method = "lm",
              color = "black",
              se = FALSE) +
  theme_light() +
  scale_color_viridis_c()              # let's use some nicer colors
```

```
`geom_smooth()` using formula = 'y ~ x'
```

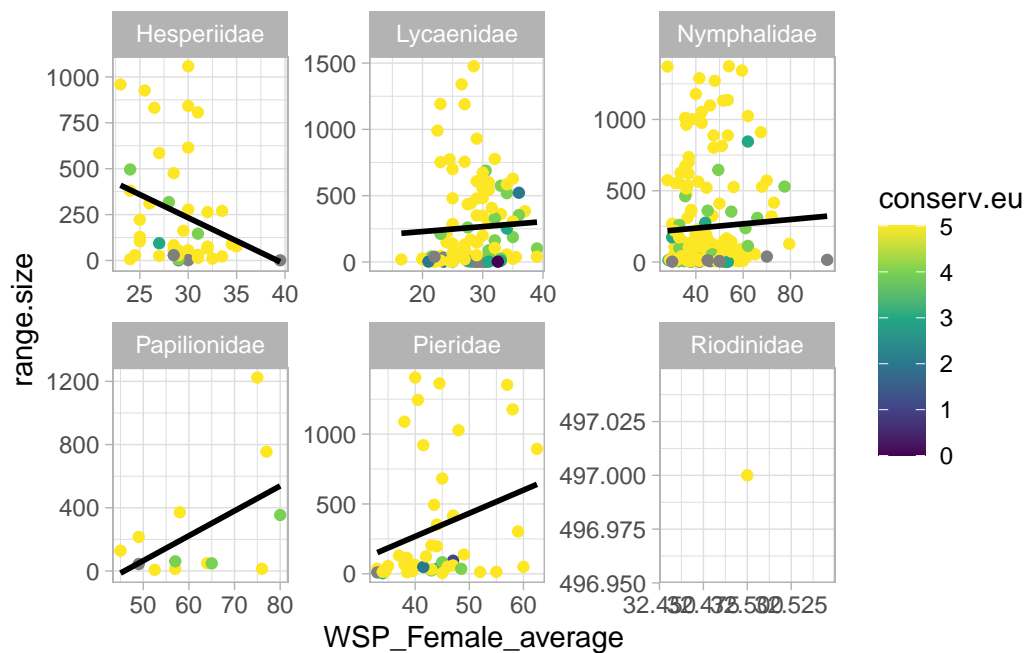

Aesthetics can be added through colors or shapes

5.3 Faceting

So far, we have cramped as much information as possible into the plot. This was useful to illustrate the functionality of `ggplot2`, but did not create very readable plots. Often, faceting is a better solution. The implementation in `ggplot2` is very straightforward.

```
# Same example as before, faceted over family
be %>%
  ggplot(aes(x = WSP_Female_average,
             y = range.size)) +
  geom_point(aes(color = conserv.eu)) +
  geom_smooth(method = "lm",
             color = "black",
             se = FALSE) +
  theme_light() +
  scale_color_viridis_c() +
  facet_wrap(~family, scales = "free")
```

``geom_smooth()`` using formula = 'y ~ x'

```
# And now, faceting over 2 variables
be %>%
  ggplot(aes(x = WSP_Female_average,
             y = range.size)) +
  geom_point(aes(color = conserv.eu)) +
  geom_smooth(method = "lm",
             color = "black",
             se = FALSE) +
  theme_light() +
  scale_color_viridis_c() +
  facet_grid(OWS_egg ~ family, scales = "free") # faceting
```

`geom_smooth()` using formula = 'y ~ x'

The above plot would need a little ‘cleaning up’. How would you do that?

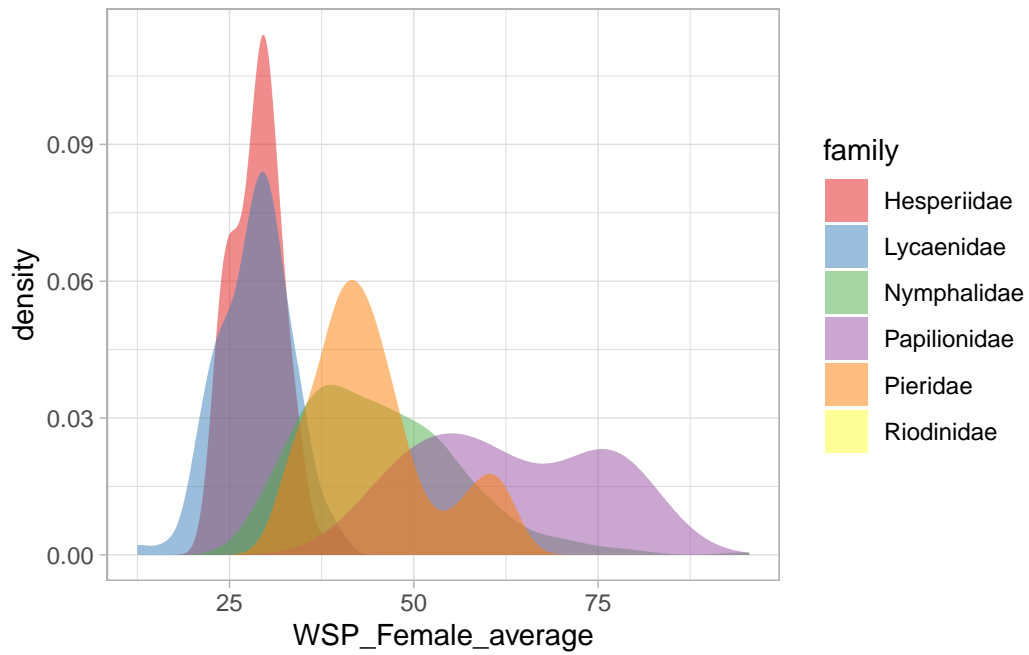

5.4 Some common plot types

We have looked at scatterplots, now let’s look at a number of other commonly used plots.

```
# histograms
be %>%
  ggplot(aes(x = WSP_Female_average, fill = family)) +
  geom_histogram(bins = 50) +
  theme_light() +
  scale_fill_brewer(palette = "Set1")
```

```
# better alternative are often density plots
be %>%
  ggplot(aes(x = WSP_Female_average, fill = family)) +
  geom_density(alpha = 0.5, colour = NA) +
  theme_light() +
  scale_fill_brewer(palette = "Set1")
```

```
# boxplots  
be %>%  
  ggplot(aes(y = WSP_Female_average, x = family)) +  
  geom_boxplot() +  
  theme_light()
```

```
# better alternative are violin plots
be %>%
  ggplot(aes(y = WSP_Female_average, x = family)) +
  geom_violin(draw_quantiles = c(0.25, 0.5, 0.75)) +
  theme_light()
```

5.5 Fine tuning plots

We now know how to plot some common chart types but most of these don't look publishable yet. Lets return to one of our first examples and see how to polish it a little.

```
# A publication ready plot
be %>%
  filter(family != "Riodinidae") %>%
  ggplot(aes(y = WSP_Female_average, x = family, color = family)) +
  geom_boxplot(lwd = 1, outlier.shape = NA) +
  geom_point(position = position_jitterdodge(jitter.width = 2), alpha = 0.5) +
  theme_light() +
  labs(title = "Wing span across European butterfly families",
       y = "Average wing span of female")+
  theme(plot.title = element_text(face = "bold"),
        axis.title.y = element_text(size = 12),
        axis.title.x = element_blank(),
        axis.text.x = element_blank(),
        strip.text = element_text(size = 11)) +
  scale_color_brewer(palette = "Set1", name = "Family")
```

Wing span across European butterfly families

5.6 Exercise

Using `ggplot2`, explore how range size differs between butterfly families and plot check if butterflies with smaller ranges have higher protection status. Try to find appropriate plot types for this, use the help pages to find plot types that were not introduced to you yet. Explore other variables that may explain some trends in the data. Find a theme that you like! Remember, start with the **data**, add **aesthetics (what do you want to plot)**, and then think about **geometric objects (how do you want to plot the data)**. How can colour help in your visualisations? Does faceting make sense?

Part II

UNIX

6 Introduction to Linux Environment and Command Line.

6.1 The Unix / Linux environment

Unix and Linux (a variant of Unix) are operating systems (like Windows or macOS). They belong to a “family” of operating systems that share a common ancestor, have been around since 1969 and it’s not likely to disappear any time soon.

- Commonly used among the scientific and technical community (e.g. servers and scientific clusters).
- macOS is Unix-based system.
- Most supercomputers are powered by Unix-like operating systems.

6.2 Why learn Unix command line?

- Is the foundation of scientific computing (e.g. bioinformatics and data analysis)
- Powerful for working on large datasets and files
- Helps automate repetitive tasks (e.g. imagine you need to need to rename or modify 1,000 files?)
- Enables use of higher-powered computers elsewhere (clusters and servers/cloud-computing)

6.3 Some terminology

Figure 6.1: image1.png

As a user you can “communicate” with your Linux system either by a **Graphical User Interface (GUI)** or by typing instructions (commands) using a **Command Line Interface (CLI)**. At first it might look quite complex and confusing but once you understand the concept and the basics then its quite simple and intuitive!

Command Line: is the written instructions we type.

Terminal: also known as terminal emulator is the text-based environment (software) capable of taking input and providing output.

Shell: a program that interprets command-line input and executes commands. There are different shells available e.g bash, zsh, sh, csh etc. Each of them offering unique features and functionalities. Some are more basic and some are more fancy but all serve the same purpose, to interpret the commands provided by the user and output the results. The most commonly used is the **bash** shell.

6.4 Some important rules

1. **Be aware of the case!** The command line is case sensitive so be careful when typing. For example, typing **Echo** is not the same as **echo**, nor are the directory names “**/Results**” and “**/results**”.
2. **Spaces are having special use!** The command line uses spaces as separators between arguments. Using spaces in filenames or directory names will certainly cause problems sooner or later. Avoid using names that contain spaces, but rather it’s better to use

dashes (-) or underscores (_). e.g., “`results_2026.txt`” is preferred over “`results 2026.txt`”.

3. Apart from spaces there are several other characters (special characters) that can be used to perform special operations. See some examples below.

| Character | Description |
|-----------|--|
| / | Directory separator, used to separate a string of directory names. Example: <code>/usr/src/linux</code> |
| \ | Escape — (backslash) prevents the next character from being interpreted as a special character. This works outside of quoting, inside double quotes, and generally ignored in single quotes. |
| . | Current directory. Can also “hide” files when it is the first character in a filename. |
| .. | Parent directory |
| ~ | The tilde is a representation of the current user’s home directory. |
| * | Represents 0 or more characters in a filename, or by itself, all files in a directory. |
| ? | Represents a single character in a filename. |
| \$ | Expansion — introduces various types of expansion: parameter expansion (e.g. <code>\$var</code> or <code>\${var}</code>), command substitution (e.g. <code>\$(command)</code>), or arithmetic expansion (e.g. <code>\$((expression))</code>). More on expansions later. |
| [] | Can be used to represent a range of values, e.g. <code>[0-9]</code> , <code>[A-Z]</code> , etc. Example: <code>hello[0-2].txt</code> represents the names <code>hello0.txt</code> , <code>hello1.txt</code> , and <code>hello2.txt</code> |
| | Pipe — send the output from one command to the input of another command. This is a method of chaining commands together. Example: <code>echo “Hello beautiful.” grep -o beautiful.</code> |
| > | Redirect output of a command into a new file. If the file already exists, over-write it. Example: <code>ls > myfiles.txt</code> |
| » | Redirect and appends the output of a command onto the end of an existing file. |
| < | Redirect a file as input to a program. |

| Character | Description |
|-----------|--|
| ; | Command separator. Allows you to execute multiple commands on a single line. Example: cd /var/log ; ls -l |
| && | Command separator as above, but only runs the second command if the first one finished without errors. |
| & | Background – when used at the end of a command, run the command in the background (do not wait for it to complete). |
| # | Comment — the # character begins a commentary that extends to the end of the line. Comments are notes of explanation and are not processed by the shell. |

6.5 Accessing your Terminal

You are using a **Kubuntu** Linux system. In Kubuntu, the terminal emulator is called **Konsole**. You can start it in any of the following ways:

1. Press **Ctrl + Alt + T** to open **Konsole** instantly.
2. Open the **Krunner** by pressing **Alt + Space**, type **Konsole**, then press **Enter**.
3. Open the **Application Launcher** → **System** → **Konsole**.

Now you are ready to start typing your first commands!

7 Part 1. Your first Unix commands - Navigating the Unix File-System Structure

What will be cover:

1. The Unix file-system structure and how to navigate
2. Some general rules
3. Relative vs absolute path
4. Running some basic commands and general syntax

Unix systems, like most operating systems, store file locations in a hierarchical structure. In the UNIX file-system each file and directory has its own “address”, and that address is called a “**path**”.

There are two special locations in all Unix-based systems That you should be familiar. The “**root**” location is where the address system of the computer starts. The “**home**” location is where the current user’s location starts.

By default every time you open a new terminal you start in your own “**home**” directory(containing files and directories that only you can modify). The path of home directory is usually represented by the “~” character.

Figure 7.1: image2.png

Basic commands we will use

| Command | Description |
|---------------------|-------------------------|
| <code>pwd</code> | print working directory |
| <code>ls</code> | list items in directory |
| <code>cd</code> | change directory |
| <code>cd ..</code> | go one level up |
| <code>ls -l</code> | long format listing |
| <code>ls -lh</code> | human readable sizes |

7.1 Finding out where you are

The `pwd` command in Linux is short for *print working directory*. It's only function is to print the absolute path of the current directory. It's handy when you're not exactly sure what directory you're in. So make it a good habit to get used to running the `pwd` command a lot.

```
# Example. Try running pwd. What do you see?
pwd
# What do you see if you run PWD instead?
PWD
# Try now to run this "echo $PWD". The command echo just prints the parameters we give it. Try
echo $PWD
```

7.2 The command `ls`

`ls` is short for *list*, and is used to list the files and sub-directories in your present working directory or some other directory if you specify one.

```
# Examples
# List the files and directories in your current directory
ls
# or
ls .
# ls can accept several options. Try running the following commands and observe how their output
ls -l
# or
ls -lh
# You can use ls to list the contents of any directory. Try the following.
ls -l /etc
```

Note

I. The anatomy of a command (or command syntax)

Each command is usually composed of three parts:

1. **The command** itself
2. **The options:** These are optional parameters that can be used to customise the behavior of a command. (e.g. on the previous examples `ls -l` shows the list of files in a long format)
3. **The arguments:** specify the target of the command. (e.g. on the previous example `ls -l /etc` you instructed the command to list the contents of the `/etc` directory)

II. Getting help

Most Unix commands can accept several parameters. How do we know which ones to use and why? Luckily, most Unix commands have built-in help documentation that we can access by providing `-help` as the only argument.

Try for example: `ls --help`

Another way to access the documentation for a command is by using the `man` command and providing the command's name as an argument. For example:

```
man ls
```

7.3 Relative vs absolute path and getting help

There are two ways to specify the path (the file's address on the computer):

- An **absolute path** starts from a fixed location, either the root directory (/) or the home directory (~). Note: A “full path” usually refers to an absolute path that starts from the root (/).
- A **relative path** starts from your current directory.

When working at the command line, it's important to always be aware of your current location in the system. One of the most common mistakes is trying to operate on a file that isn't where you think it is. To avoid this, it's good practice to use absolute paths, which clearly specify a file's exact location regardless of where you are.

7.4 Moving around

One of the most commonly used commands in Linux is the ***change directory*** command, or `cd`. It allows you to change your working directory from the current location to another directory you want to navigate to. The `cd` command takes a positional argument: the path (address) of the directory you want to move into. This path can be either **absolute** or **relative**. Let's try moving from our current directory to a directory present in your home directory called *Documents*.

```
# The relative way
cd Documents
# The absolute way (~ stands for /home/<user>/). Can you see the change in your command prompt?
cd ~/Documents
# But how do we go back "up" to the parent directory? We can use the ".." special characters
cd ..
# When you need to navigate back to the previous working directory from the current working directory
cd -
# Note: running the cd command without any arguments will always bring you back to your home directory
cd
```

7.5 Exercise

Practice moving around the filesystem with `cd` and listing directory contents with `ls`, including navigating by relative and absolute paths or using special characters “`..`” . Use `pwd` frequently to see your current working directory. Practice navigating home with `cd`.

8 Part 2. Working with Files and Directories

What we will cover:

1. Working with simple text files
2. Working with directories
3. Intro to a command-line text editor

8.1 Creating new directories and files

You can create a new directory using the **mkdir** command. It takes as a parameter a relative or absolute path to the directory to create

```
# Let's try some examples. From your home directory navigate to Documents/ and create 2 new r
pwd
cd Documents
mkdir projects
cd projects
mkdir projects1
pwd
# Try to create a new directory with the same name e.g. projects1. What do you see?
```

Exercise

In the previous example we created the two directories in two separate steps. Can we do it in one step instead? (check the help page for **mkdir** command).

Now that we saw how to create a new directory lets see how we can create a new file. There are several ways to do this in Linux command line but we will start with the basic one. The command **touch** will create a new, empty file.

```
# Create an Empty File within the new directory project1.
touch notes.txt
# can you do it if you are outside the project1 directory?
```

8.2 Move or Rename a File or Directory

The **mv** command serves for both moving and renaming files and directories. Works by specifying a “source_path” and a “destination_path”, where “source_path” is the path (absolute or relative) of the file/directory to move or rename, and “destination_path” is the new name or location to give it.

Copying files and directories is similar operation, except that the original file or directory is not removed! We will use the **cp** command for this.

NOTE: copying, moving or renaming files at the command line will overwrite files if they have the same name!!

Let’s try them both.

```
# move the notes.txt file one directory up assuming your current directory is project1
mv notes.txt ../notes.txt
# rename the notes.txt to README.txt
mv ../notes.txt ../README.txt
# copy the README.txt file to project1 directory as README1.txt
cp ../README.txt ../README1.txt
```

Exercise

Try to make a copy of the complete project1 directory on the same parent location with the name project2. What do you see?

Note

Wildcards: friend and foe at the command prompt.

As we saw earlier some characters have special use in Unix command line. For example:

- the asterisk character “*” represents 0 or more characters in a filename, or by itself, all files in a directory.
- the square brackets [...] can be used define a range of values e.g. [0-9], [A-Z], etc.
- the question mark “?” can represent any single character.

These characters can be used as “Wildcards” to perform operations on multiple files at the same time. Lets see some examples.

```
# Create a directory with the name wildcard_practice and, inside it, create some empty files
mkdir wildcard_practice
cd wildcard_practice
touch file1.txt file2.txt file10.txt
touch image1.png image2.png imageA.png
touch data_2022.csv data_2023.csv data_2024.csv
# List all the .txt files
ls *.txt
# create a directory called data and move the .csv files into data/
mkdir data
mv *.csv data/
```

Exercise List only the .csv files with years 2022 or 2023

8.3 Delete (remove) files and directories

WARNING!!

Using the `rm` command permanently deletes files and directories without moving them to a trash or recycle bin. This action cannot be undone! Whenever you use the `rm` command, ALWAYS double-check your syntax.

```
# Lets remove some unwanted files and directories
rm ~/Documents/projects/README.txt
# the command rmdir can remove an empty directory, so it is safer!
mkdir test_dir
rmdir test_dir
# The dangerous way. Use rm recursively "-r" to remove a non-empty directory. BE CAUTIOUS! YOU CAN LOSE DATA!
rm -r ~/Documents/projects/project1
# check the help page for rm command. Is there a safer way to do this?
```

Exercise

1. Create a directory `data`.
2. Inside `data`, create three empty files: `sample1.txt`, `sample2.txt`, `sample3.txt`
3. Copy `sample1.txt` into a new directory called `backup`.
4. Rename `sample2.txt` to `s2.txt`.
5. Remove `sample3.txt`.

8.4 Viewing and inspecting Files

Sometimes we want to quickly look at files, either to inspect their structure or to get some basic information about their contents. These are some commands we can use to do so.

| Command | Description |
|-------------|-------------------------------------|
| cat | print entire file |
| less | scroll through file |
| head | show first n lines |
| tail | show last n lines |
| wc | count (w ord c ount) |

```
# Lets use the file "butterfly_ecology.csv" you previously used with R.
# You can either navigate to the folder you saved the file copy it to a new directory.
# You can use the "cat" command for viewing the contents of a file
cat butterfly_ecology.csv
# Another command for viewing the contents of a file is "less". This command allows to scroll
less butterfly_ecology.csv
# However, most of the time we only need to see part of a file rather than the entire file.
head butterfly_ecology.csv
tail butterfly_ecology.csv
# or you can specify the number of lines to print (by default will print 10)
head -n 2 butterfly_ecology.csv
tail -n 3 butterfly_ecology.csv
# The command wc (word count) is useful for counting how many lines, words, and characters there are
wc butterfly_ecology.csv
# Can you find an option for wc that will let us get only the number of lines of the file?
```

Note

The **cat** command can also be used to create new files or to concatenate existing files. Lets try:

```
cat > file1
Stefanos
# Exit by pressing Ctrl + D
cat > file2
some random text
# Exit by pressing Ctrl + D
cat file1 file2 > file3
```

8.5 A text editor for the terminal

A simple text editor available on most systems is nano. To run it, simply specify a file name to edit. If the file doesn't exist already, it will be created after saving.

```
nano NOTES.txt
```

9 Part 3. Redirection, Pipes, and Text Processing in Unix

9.1 Redirecting and piping

Redirection and piping are fundamental features of the UNIX command line that allow us to create powerful workflows for automating tasks. By default, when we run a command, its output is printed to the screen (the terminal). In many situations, however, we may want to save this output to a file or pass it directly to another command.

We have already seen how a command output can be redirected to a file. For example: `cat file1 file2 > combined_file`. In this command, the redirection operator `>` tells the shell to send the output of `cat` to a new file called `combined_file` instead of displaying it on the screen. Let look at another example.

```
# list the files in the /etc directory and save the output to a file called etc_content.txt.  
ls /etc > etc_content.txt  
less etc_content.txt
```

WARNING!!

It's important to remember that the `>` operator will overwrite a file if it already exists. If you want to append an output to an existing file, rather than overwrite it, you can use instead `>>`.

- Try it out yourself!

While redirection allows us to save a command's output to a file, UNIX also allows us to connect commands directly to one another. We can send the output of one command directly as input to another using the pipe (`|`) operator.

```
#list only the first 10 files of the /etc directory  
ls /etc | head -n 10
```

Exercise

- Using the pipe operator, find a way to count all contents (files and directories) in the /etc directory.

9.2 cut, sort, and uniq

The `cut` command is used for extracting specific sections from lines of text in a file or piped data. It's a great tool for data manipulation. Let's try some examples:

```
# Selecting fields separated by a delimiter
echo "name,age,city,country" | cut -d ',' -f 3
# lets manipulate some real data
cat butterfly_ecology.csv | cut -d ',' -f 1,2 | head
# you can even change the delimiter in the output
cat butterfly_ecology.csv | cut -d ',' -f 1,2 --output-delimiter $'\t' | head
# or
cat butterfly_ecology.csv | cut -d ',' -f 1,2,5-7 --output-delimiter $'\t' | head
```

The `sort` command is used to arrange the lines of text files in a specified order, such as alphabetically or numerically. It can also handle options for sorting in reverse order or by specific columns. NOTE: `sort` command will not modify your file, it will only print the reordered content on the terminal! However, you can specify redirect the output to a separate file.

```
cat butterfly_ecology.csv | cut -d ',' -f 1-3 | sort
cat butterfly_ecology.csv | cut -d ',' -f 1-3 | sort -t ',' -k3 | less
```

The `uniq` command in Linux is used to filter out repeated lines from a text file or standard input, displaying only unique entries or counting repetitions. It works best when the input is sorted, as it only removes adjacent duplicate lines.

```
# families are represented in the butterfly_ecology.csv data?
cat butterfly_ecology.csv | cut -d ',' -f 2 | sort | uniq
```

Exercise

- Can you use `cut`, `sort` and `uniq` commands to count the number of species per family?

9.3 grep and regular expressions

The **grep** (global regular expression) command in Linux is used to search for specific patterns or strings within files and display the matching lines. It is a powerful tool for text processing and can be customized with various options to refine search results. The basic usage is: **grep** “*searchword*” *filename*

```
# Let's say you wished to identify every line which contain the string "Papilionidae" from the
grep 'Papilionidae' butterfly_ecology.csv
# We can find the number of lines that matches the given string/pattern instead
grep -c 'Papilionidae' butterfly_ecology.csv
# Use -f option to read patterns from a file
cat > family.txt
Papilionidae
Hesperiidae
# exit by pressing Ctrl + D
grep -f family.txt butterfly_ecology.csv
# We can search for patterns in multiple files (e.g. all the files in the directory)
grep 'Papilionidae' *
```

grep command is particularly powerful when used in combination with Regular Expressions. A regular expression (regex) in Linux is a sequence of characters that defines a search pattern, similar to the wildcards, and are commonly used for searching and manipulating text.

Exercises

- In the `butterfly_ecology.csv` file find all “Aglais” species and save the fields `species`, `family`, `range.size` in a new file.
- The shell keeps a record of the commands you have previously run. You can display this list using the `history` command. Using this information, determine how many times you have used the `ls` command in your shell history. Hint: You may need to combine `history` with other command-line tools such as `grep`.

9.4 awk

awk is the Unix command to work with tabular data. The basic **awk** syntax is: **awk** [options] ‘pattern {action}’ input-file > output-file

```

awk -F ',' '{print $0}' butterfly_ecology.csv

awk -F ',' '$3 > 1000 && $3 != "NA" {print $0}' butterfly_ecology.csv

awk -F ',' '$3 > 1000 && $3 != "NA" {print $1, $3}' butterfly_ecology.csv

awk -F ',' '{if($3 > 1000 && $3 != "NA") {print $1 "::" $3}}' butterfly_ecology.csv

```

A more complex example

Using only command line try calculate the average range.size for each family separately and store this information in a new file.

```

grep -v "^species" butterfly_ecology.csv | \
awk -F ',' '
$3 != "NA" {
    sum[$2] += $3
    count[$2]++
}
END {
    for (family in sum) {
        print family, sum[family] / count[family]
    }
}
' OFS=' ' > average_range_by_family.csv

```
